

Pusher syndrome — lesion localization (left OR right hemisphere)

A. Axial section — thalamic level

B. Lateral view — secondary cortical sites

Damage to the body-graviceptive relay tilts the felt body-upright (SPV) $\sim 18\text{--}20^\circ$ toward the lesion side, in the coronal (roll) plane; the patient then pushes contralesionally. Visual vertical (SVV) stays normal.

Primary lesion: posterolateral thalamus

Secondary ($\pm$, esp. if thalamus spared): insula / postcentral gyrus
